(Dated: July 29, 2008)

Upper limits on the production cross section for neutral Higgs bosons decaying into $\tau^+\tau^-$ final states are presented from $p\bar{p}$ collisions at a center-of-mass energy of 1.96 TeV. The integrated luminosity for the study is about 2.2 fb$^{-1}$, collected by the DØ Experiment at the Fermilab Tevatron Collider during Run IIa and Run IIb. The results are interpreted in the Minimal Supersymmetric Standard Model (MSSM), and regions in the ($m_A$, $\tan\beta$) parameter space for two MSSM benchmark scenarios are excluded.
I. COMBINED LIMITS ON CROSS-SECTION

Searches for neutral Higgs bosons decaying into tau lepton pairs, \( \phi (= H, h, A) \rightarrow \tau \tau \), have been performed by the DØ Collaboration with integrated luminosities of \( \mathcal{L} = 1.0 \) fb\(^{-1}\) in Run IIa [1] and \( \mathcal{L} = 1.2 \) fb\(^{-1}\) in Run IIb [2]. The Run IIa search requires the tau pairs to decay into \( \tau e\mu\text{had} \), \( \tau \mu\text{had} \), or \( \tau e\tau \mu \), and the Run IIb search requires the tau pairs to decay into \( \tau \mu\text{had} \), where \( \tau e \) and \( \tau \mu \) are the leptonic decays of the tau and \( \tau \mu \) is the hadronic decay mode. In these studies, which together represent a dataset of \( \mathcal{L} = 2.2 \) fb\(^{-1}\), no significant excess in signal over background has been observed and thus limits on the production cross section for neutral Higgs boson times the branching fraction into tau leptons are given for neutral Higgs bosons in the range of 90 to 300 GeV. The visible mass, \( M_{\text{vis}} \), spectrum, shown in Fig. 1 and defined in [1, 2], is used in the limit calculation. These limits are shown in Fig. 2 in comparison to rates for a Higgs boson with Standard Model (SM) width. Correlations in systematic uncertainties between the different tau decay channels that have been studied are taken into account. The combination of the 2.2 fb\(^{-1}\) dataset analyzed at DØ in Run II provides a 10-20\% improvement in the cross section across the range of Higgs boson masses studied.

II. INTERPRETATION OF RESULTS IN MSSM

From the cross section limits for neutral Higgs production regions of the \((m_A, \tan\beta)\) parameter space can be excluded in the Minimal Supersymmetric Standard Model (MSSM). Through radiative corrections beyond tree level, the masses and couplings of the Higgs boson depend on additional SUSY parameters. Assuming a CP-conserving Higgs sector, limits on \( \tan\beta \) as a function of \( m_A \) can be derived in two benchmark scenarios given by:

- \( m_h^{\text{max}} \) scenario:
  * \( X_t = 2 \) TeV;
  * \( \mu = \pm 0.2 \) TeV;
  * \( M_2 = 0.2 \) TeV;
  * \( m_{\tilde{g}} = 0.8 \) TeV
  * \( M_{\text{SUSY}} = 1 \) TeV
FIG. 2: Expected and observed upper limits on the production cross section times branching ratio for $\phi \rightarrow \tau\tau$ production as a function of $m_{\phi}$ assuming the SM width of the Higgs boson on (a) a linear scale and (b) a log scale. Results (square marker) correspond to an integrated luminosity of $L=2.2 \text{ fb}^{-1}$ and are compared to the DØ Run IIa $L=1.0 \text{ fb}^{-1}$ result (asterisk marker).

- No-mixing scenario:
  
  $* X_t = 0 \text{ TeV};$
  $* \mu = \pm 0.2 \text{ TeV};$
  $* M_2 = 0.2 \text{ TeV};$
  $* m_{\tilde{g}} = 1.6 \text{ TeV};$
  $* M_{\text{SUSY}} = 2 \text{ TeV}$

where $X_t$, $\mu$, $M_2$, $m_{\tilde{g}}$, and $M_{\text{SUSY}}$ are the mixing parameter, Higgsino mass parameter, gaugino mass term, gluino mass, and the common scalar mass, respectively.

The cross section, width, and branching ratios for the Higgs boson have been calculated using the FEYNHIGGS program [3] version 2.6.4. The excluded region in the $(m_A, \tan\beta)$ space in each scenario is given in Fig. 3, for the case of $\mu > 0$. The region excluded by the LEP experiments [5] is also shown. The $\mu < 0$ case, which is presently disfavored [4], is not considered. At large $\tan\beta$, the $A$ boson is nearly degenerate in mass with either the $h$ or $H$ boson and thus, the production cross sections for $gg \rightarrow A$ and $b\bar{b} \rightarrow A$ are added at each $(m_A, \tan\beta)$ point.

Acknowledgments

We thank the staffs at Fermilab and collaborating institutions, and acknowledge support from the DOE and NSF (USA); CEA and CNRS/IN2P3 (France); FASI, Rosatom and RFBR (Russia); CNPq, FAPERJ, FAPESP and FUNDUNESP (Brazil); DAE and DST (India); Colciencias (Colombia); CONACyT (Mexico); KRF and KOSEF (Korea); CONICET and UBACyT (Argentina); FOM (The Netherlands); STFC (United Kingdom); MSMT and GACR (Czech Republic); CRC Program, CFI, NSERC and WestGrid Project (Canada); BMBF and DFG (Germany); SFI (Ireland); The Swedish Research Council (Sweden); CAS and CNSF (China); and the Alexander von Humboldt Foundation (Germany).

FIG. 3: Region in the ($m_A$, $\tan\beta$) parameter space that has been excluded at 95% CL for $\mu > 0$ in two MSSM benchmark scenarios: (a) $m_A^{\text{max}}$ and (b) no-mixing. Shown also by the green shaded region is the excluded region by LEP [5].
